

Supplementary information for
Improving extinction projections across scales and habitats using the
countryside species-area relationship

Contents:

Note: Relation between sensitivities (σ) and affinities (h).

Figure S1: Effect size analysis.

Figure S2: Scheme exemplifying how the simulated landscapes were sampled.

Figure S3: Proportion of species extinctions in the simulated landscape after habitat conversion given by the linear, classic SAR and the countryside SAR.

Figure S4: Proportion of species extinctions in the simulated landscape after 90% habitat conversion given by the linear, classic SAR and the countryside SAR, when varying the degree of fragmentation of the landscape after habitat conversion.

Table S1: Local sensitivities (σ) for each land use type.

Table S2: Average affinity values (h 's) for the different habitats and regions of the world.

Supplementary Note

Here we show, in greater detail than in the main text, that sensitivities (σ) and affinities (h) are related. If one assumes full habitat conversion ($A - a = 0$ and $a = A$), and that species have maximum affinity for the native habitat, $h_1 = 1$, the affinity of a species group to the habitat of type j , can be derived with equation (3) in the main text:

$$\varepsilon(a) = \frac{S(A, 0) - S(0, A)}{S(A, 0)} = 1 - \left(\frac{h_j A}{A} \right)^z = 1 - h_j^z. \quad (1)$$

Knowing that, σ_j equals ε (equation (3)) at the plot scale when the native habitat is fully converted to habitat j (i.e. $a = A$):

$$\sigma_j = 1 - h_j^z. \quad (2)$$

Thus, it is straightforward to show that:

$$h_j = (1 - \sigma_j)^{1/z}. \quad (3)$$

Supplementary Figures

Supplementary Figure S1. Effect size (eta squared - η^2) and their confidence intervals (95% CIs) for the different categorical variables (i.e., taxa, region and land use) and their interactions analysed with a three-way ANOVA (N=730).

Supplementary Figure S2. Scheme exemplifying how the simulated landscapes were sampled to calculate the average proportion of species extinctions $\bar{\varepsilon}(\Omega)$, at each sampling grain, Ω . (a) potential configuration of a simulated landscape, illustrated for a $4 \times 4 = 16$ grid, with white squares corresponding to human-modified habitat and grey squares to the native habitat. (b) three different sampling grains: at the small sampling grain, sampling window k is only comprised of 1 cell ($\Omega = 1, N(\Omega) = 16$), at the intermediate sampling grain, sampling window k is comprised of 4 cells ($\Omega = 4, N(\Omega) = 4$) and at the large sampling grain, there is only one sampling window k and comprises all cells ($\Omega = 16, N(\Omega) = 1$). (c) For a given model (see Methods), species extinctions, $\varepsilon(a_k^\Omega)$, were calculated for each sampling window k of size Ω in the landscape (d) At each sampling grain, the projections of each sampling window were averaged to obtain the overall fraction of species going extinct in the landscape, where $\bar{\varepsilon}(\Omega) = \frac{\sum_k \varepsilon(a_k^\Omega)}{N(\Omega)}$.

Supplementary Figure S3. Proportion of species extinctions (ϵ) in the simulated landscape after habitat conversion given by the linear, classic SAR and the countryside SAR. When varying **(a)** amount of native habitat left in the landscape (when $z=0.2$ and $h_2=0.01$), **(b)** the z -value (for 10% habitat remaining and $h_2=0.01$) and **(c)** species sensitivity for the modified habitat (for 10% habitat remaining and $z=0.2$). For all scenarios, $h_1=1$ for the native habitat. Points corresponds to the average number of species (across 1000 simulations) found in all sampling units of a given sample grain.

Supplementary Figure S4. Proportion of species extinctions (ϵ) in the simulated landscape after 90% habitat conversion given by the linear, classic SAR and the countryside SAR ($z=0.2$; $h_1=1$, $h_2=0.01$). When varying (a-c) the degree of fragmentation of the landscape after habitat conversion. Right panels show examples of the configuration of a simulated landscape to the different degrees of fragmentation, with white squares corresponding to human-modified habitat and grey squares to the native habitat. For all models, $z = 0.2$, with $h_1=1$ for the native habitat and $h_2 = 0.01$ for the modified habitat. Error bars indicate for each model, the standard deviation of the fraction of species remaining at a given sample grain.

Supplementary Tables

Supplementary Table S1. Complete list of local sensitivities (σ - sigma) values. A total of 730 pairwise comparisons across two taxonomic groups (plants and birds), two broad ecological regions (tropical and temperate), and five different human-modified habitats (annual crops, managed forest, permanent crops, pastures and urban) were retrieved from the literature. Studies ('Source 2') were considered if they provided data on species richness on both a native habitat and at least one human-modified habitat. For several studies, more than one possible pairwise comparisons was reported.

Supplementary Table S2. Average affinity values (h's) for the different habitats and regions of the world.

	Tropical	Temperate
Annual crops	0.0229	0.0150
Permanent crops	0.0206	0.0219
Pastures	0.0294	0.2999
Managed Forest	0.2365	0.3584
Urban	0.0209	0.0610
